

# High Resolution Astrophotography

AIC 2009

by Volker Wendel  
[www.spiegelteam.de](http://www.spiegelteam.de)

## Content:

- I. Some theoretical thoughts
- II. What helps when starting High Resolution Imaging
- III. High Resolution Image Processing

We are looking for smallest details, but we should separate between Deep-Sky Imaging with single exposures  $>10$  seconds and planetary imaging with sub-second exposures.

**Image of Saturn and Eskimo Nebula, both at fl = 6000mm**

# Some theoretical thoughts

- usually we are talking about focal lengths  $>2000\text{mm}$
- a pixel sampling that matches the best possible seeing conditions at your observing site is needed
- roughly spoken: pixel sampling multiplied by 3 should match best seeing conditions

example: best possible seeing in the last four years in my backyard was  $1,6''$  FWHM so my telescope and CCD-camera setup should give me a sampling of about  $1,6/3=0,53''$

my reality:  $15''$ -Newtonian with a special made APO-barlow lens gives me a focal length of about  $3000\text{mm}$ . ST10XME in use, pixel size  $6,8\mu\text{m}$

# Formula to calculate pixel sampling

$$\frac{\text{pixelsize (mm)}}{\text{focal length (mm)}} \times 57,3 \times 3600$$

In my example:

$$\frac{0,068 \text{ mm}}{3000 \text{ mm}} \times 57,3 \times 3600 = 0,45'' \text{ per pixel}$$

⇒ perfect match for seeing conditions up to  $(0,45'' \times 3 =) 1,35''$

⇒ in about 95% not needed but able to get the maximum in best nights in my backyard

Urban observing sites have most of the time seeing conditions not better than 2", remote sites can give you seeing conditions next to 1" so you should be prepared for your given situation.

maximum seeing condition	pixel size	focal length needed
2"	6,8my	~2100mm
2"	9my	~2750mm
1"	6,8my	~4200mm
1"	9my	~5500mm
0,5"	6,8my	~7500mm
0,5"	9my	~10000mm

# Maximum Telescope Resolution

(interesting for Planetary imaging)

**Rayleigh**

$116/d = \text{max. resolution in arcsec.}$  (d = telescope aperture in mm)

Results using this formular:

100 mm	200 mm	400 mm	800 mm	5000 mm
1,16"	0,58"	0,29"	0,15"	0,023"

**Sparrow**

$70/d = \text{max. resolution in arcsec.}$  (d = telescope aperture in mm)

Results using this formular:

100 mm	200 mm	400 mm	800 mm	5000 mm
0,7"	0,35"	0,17"	0,09"	0,014"

=> not realistic for Deep-Sky Imaging but for Planetary Imaging with perfect optics

# Planetary Imaging

- modern noise free video cameras are the best way to go for lucky imaging
- telescope setups should have such a long focal length so that you are able to get your maximum resolution out of the telescope, see the sparrow and pixel sampling formula shown before
- Sparrows extreme resolution formula seems to be realistic!

**Clavius with the best lucky shot out of the ST10 and a webcam shot:**

15" at 3000mm

12" at 6000mm

My backyard observatory with the 15"-Newtonian in my backyard, mag 5.5 skies

## Telescopes used :

12"-Schiefspiegler  
fl= 6000mm  
Bernd Flach-Wilken

16"-Hypergraph  
fl= 3200mm  
Bernd Flach-Wilken

24"-Hypergraph  
fl= 4800mm  
Capella-Observatory

Where does the Spiegelteam shoot from? Germany and...

...Namibia and in cooperation with the Capella-Observatory team from Crete/Greece!

# What helps to get the best out of your telescope setup (1)?

- use perfect mirrors (including secondary!) or lenses for highest contrast

- try to get the best collimation possible
- try to make your telescope as collimation stable as possible (very useful when remotely operating)

## What helps to get the best out of your telescope setup (2)?

- try to have perfect guiding (for example with AO-Systems)
- try to hold perfect focus the whole night

- try to shoot luminance when your object is near it's highest position because of seeing

# What helps to get the best out of your telescope setup (3)?

- cool down your tube (and your dome) before starting imaging

example:

(source J.S.Schlimmer  
[www.epsilon-lyrae.de](http://www.epsilon-lyrae.de))

- optimize your local system

**Long focal length = small FOV  
=> build mosaics for larger objects**

**M33**

(1800mm, STL11k, two frames)

...or buy larger chips => but be sure, your optics are able to get a nearly coma free field, large chips are not everything!

# Seeing is everything - example of different seeing conditons

NGC 6015 @ 3"

NGC 6015 @ 1,9"

NGC 6015 @ 1,3"

## Second example of different seeing conditons

NGC 6015 with an irregular galaxy:

## Second example of different seeing conditons

Seeing animation of a irregular galaxy next to NGC 6015 in the finally processed image:

# What helps in image processing to get the maximum?

-try to get the best S/N ratio

NGC6946:

left side 16x600s

right side 1x600s

- concentrate your processing on the Luminance master to get the sharpest result

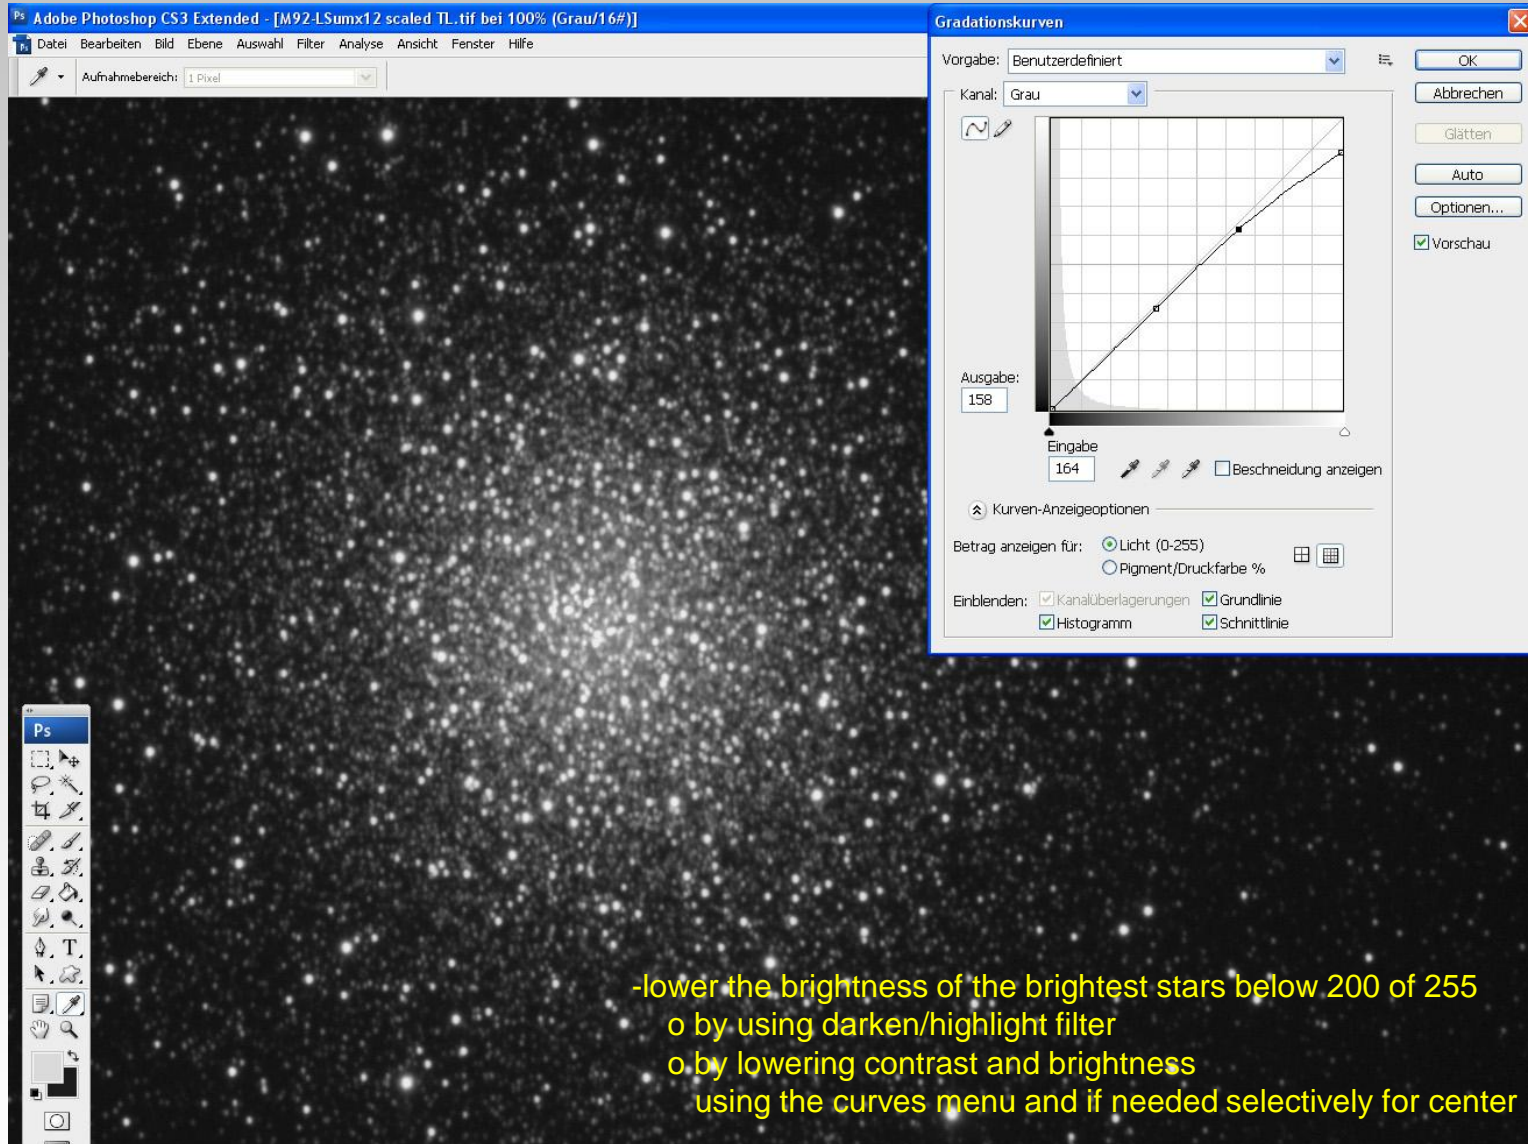

- use deconvolutions and other contrast enhancing techniques

- do not overcook your images using too much of it => artefacts destroy a good image

# High Resolution Image Processing

Globular clusters: many bright star near saturation, how to get colors in the image?

The screenshot displays the Adobe Photoshop CS3 Extended interface. The main canvas shows a globular cluster image with many bright stars. The 'Gradationskurven' (Curves) panel is open, showing a graph with a diagonal line and a curve that has been adjusted to lower the brightness of the brightest stars. The 'Ausgabe' (Output) value is set to 158, and the 'Eingabe' (Input) value is set to 164. The 'Kurve-Anzeigeoptionen' (Curve Display Options) section is expanded, showing options for 'Betrag anzeigen für:' (Amount to show for:), 'Einblenden:' (Show:), and 'Beschnittung anzeigen' (Show clipping).

Ps Adobe Photoshop CS3 Extended - [M92-LSumx12 scaled TL.tif bei 100% (Grau/16#)]

Ps

-lower the brightness of the brightest stars below 200 of 255  
o by using darken/highlight filter  
o by lowering contrast and brightness  
using the curves menu and if needed selectively for center

# Globular clusters: how to tighten up the stars without oversharpening them?

- Use the high pass filter for tightening up the stars
  - o holds the brightness of the stars the same so they still can get color
  - o unsharp masking instead would raise the brightness, this would make it harder to add color

## Star clusters: how to get good color saturation and differentiation?

1. Hold the brightest stars away from saturation as described above (if necessary, use the Burn tool selectively to the center!)
2. Raise the color saturation up to +40% but deselect the background before!
3. Raise the color contrast by S-shaping the gradations curve at the point where most of the stars have their brightness and bring down the curve in the brightest third to avoid saturation (this is the most important factor for color differentiation, even in other object classes)

# Final LRGB of M92 (in coop with Capella-Observatory team)

⇒as for bright objects, think about shooting them as a straight RGB!  
(this helps to avoid saturating stars and gives high color saturation)

# Galaxies, PN's, Nebula: what can we do to let them look „high res“?

NGC891 16x600s 1,9" average backyard in germany

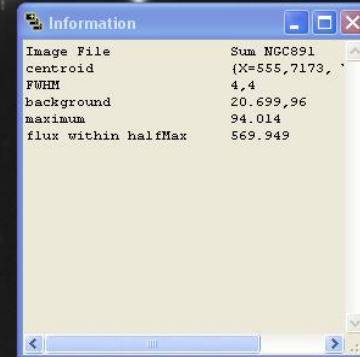

=> this image is reduced in CCDStack by using a flat, darks etc and saved as „16bit scaled data“ avoiding saturation in the object and clipping in the background

# Deconvolution (1)

Sum NGC891

File Edit Process Stack Color Window Help

CCDStack at the beginning:

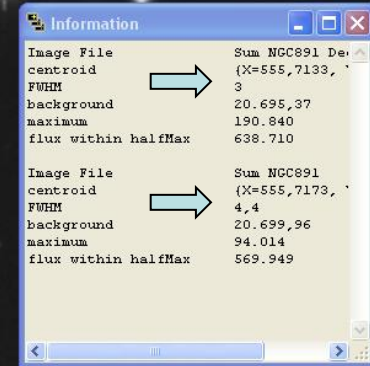

- Use „Maximum Entropy“ in a soft way to get small details and a smoother background (or directly use „Positive Constraint“)
- Hold the original raw file the same contrast to copy the original stars for a star repair later on
- Use a lower „maximum ADU“ number as suggested by CCDStack to make the deconvolution more aggressive

# Deconvolution (2)

Sum NGC891 Deconvolved

File Edit Process Stack Color Window Help

2 images: {width=2184, Height=1472} bin1x1 6.0 MP (227 MB)

Use Positive Constraint in a mild way as a 2nd deconvolution step (here the stars were reduced from FWHM 4.4 to 3 in the first step)

Animation of raw file, Maximum Entropy and finally Positive Constraint deconvolution

Reduce noise at the edges of your super sharp layer for example with Kodak GEM which I like best

# Unsharp masking

Adobe Photoshop CS3 Extended - [Sum NGC891 Scaled\_Ausgangsbild.TIFF bei 100% (super-sharp, RGB/16)]

Datei Bearbeiten Bild Ebene Auswahl Filter Analyse Ansicht Fenster Hilfe

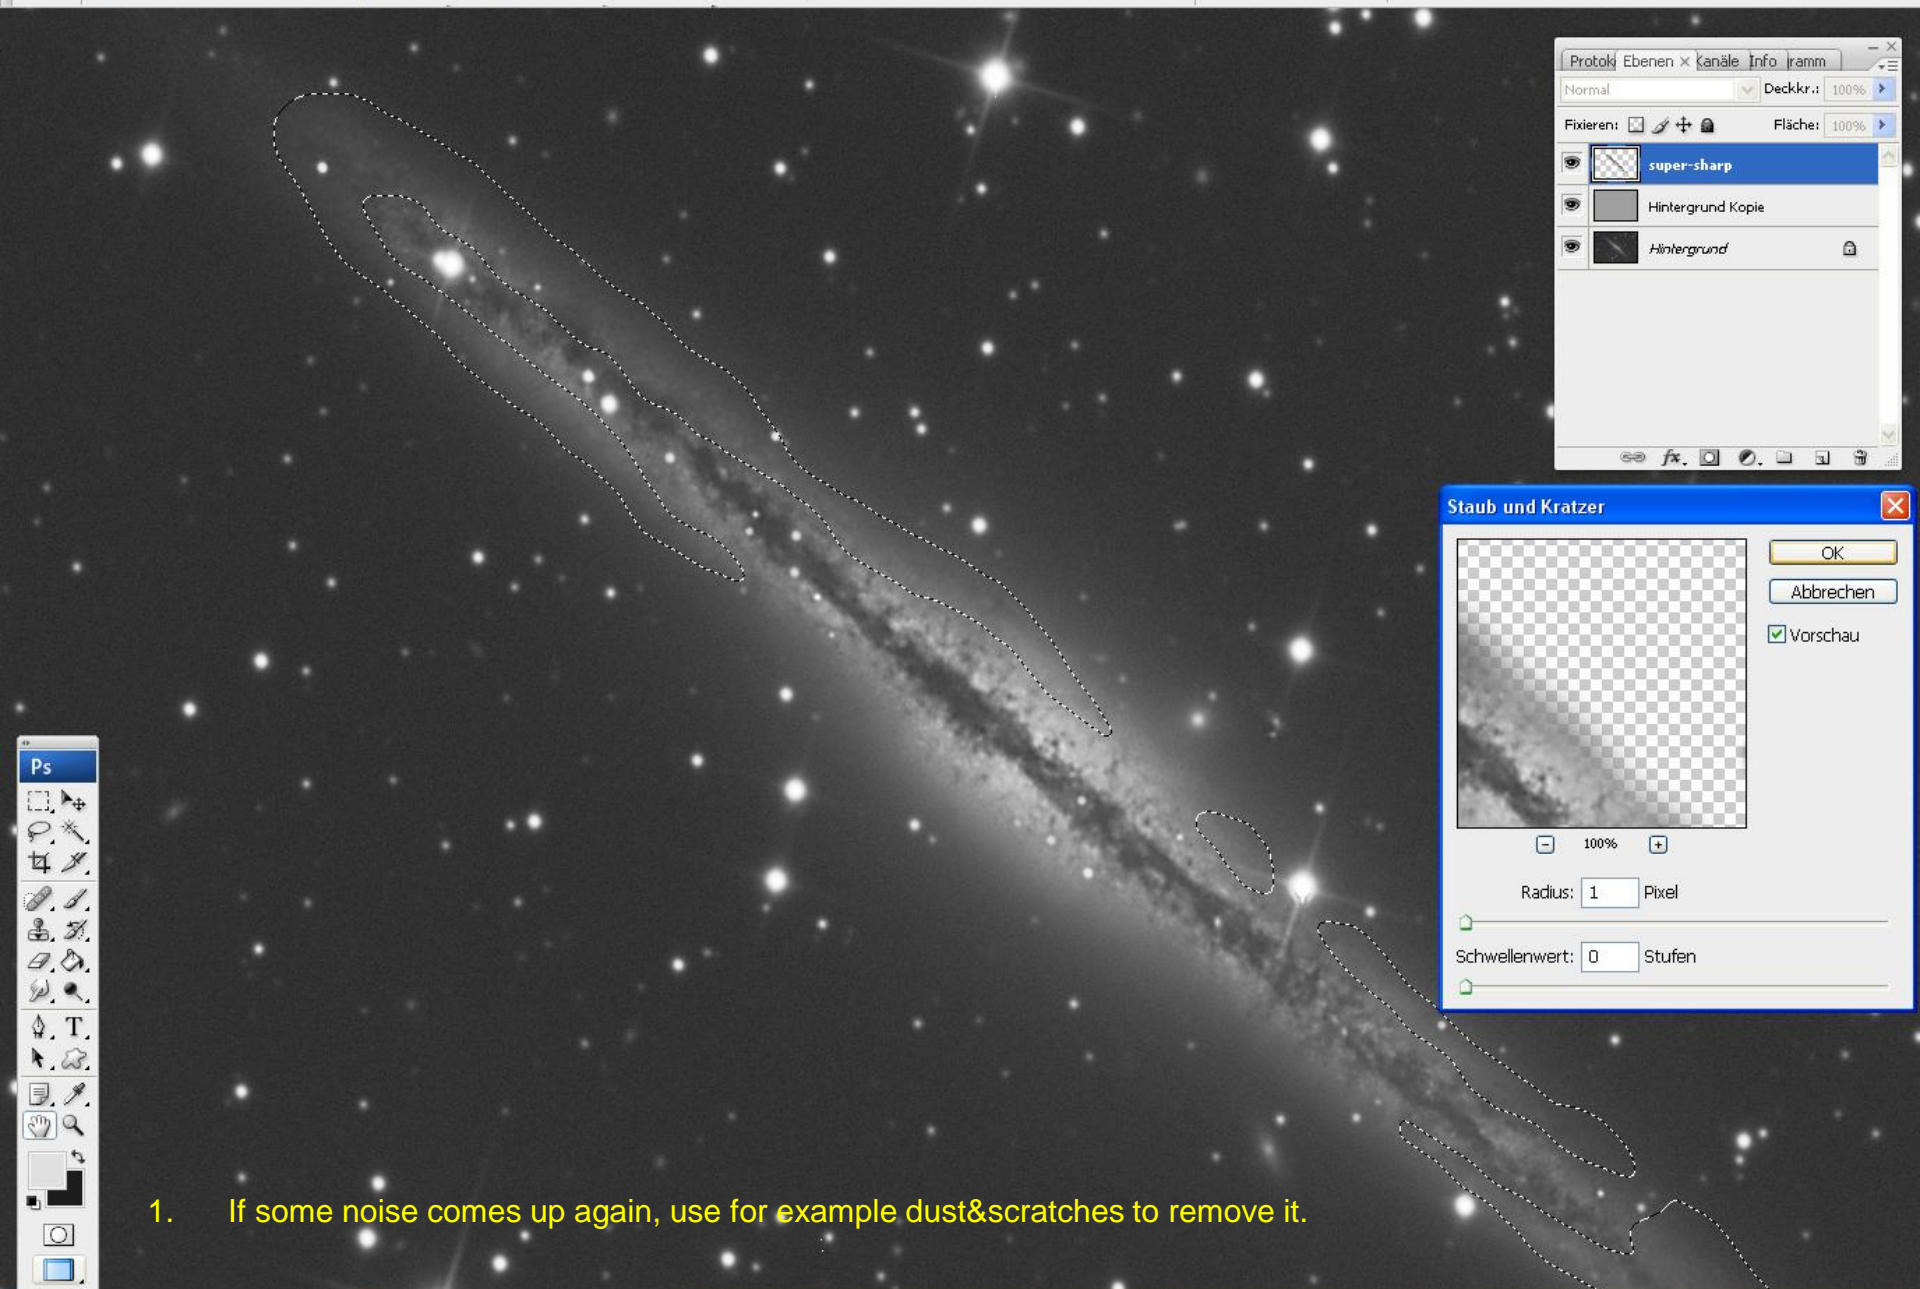

Bildlauf in allen Fenstern durchführen Tatsächliche Pixel Bildschirmgröße Druckformat

Arbeitsbereich

1. Select all the objects which you want to bring out again with more contrast (sharper look) even small objects. Deselect the stars in your selection and always use a feathered selection to avoid hard edges.
2. Use the Unsharp Mask tool in Photoshop or elsewhere and use values of about (80/2/1-3). The removal of noise in the step before now helps to allow you aggressive unsharp masking because noise is nomore a big deal.

JPEG-Artefakt entfernen

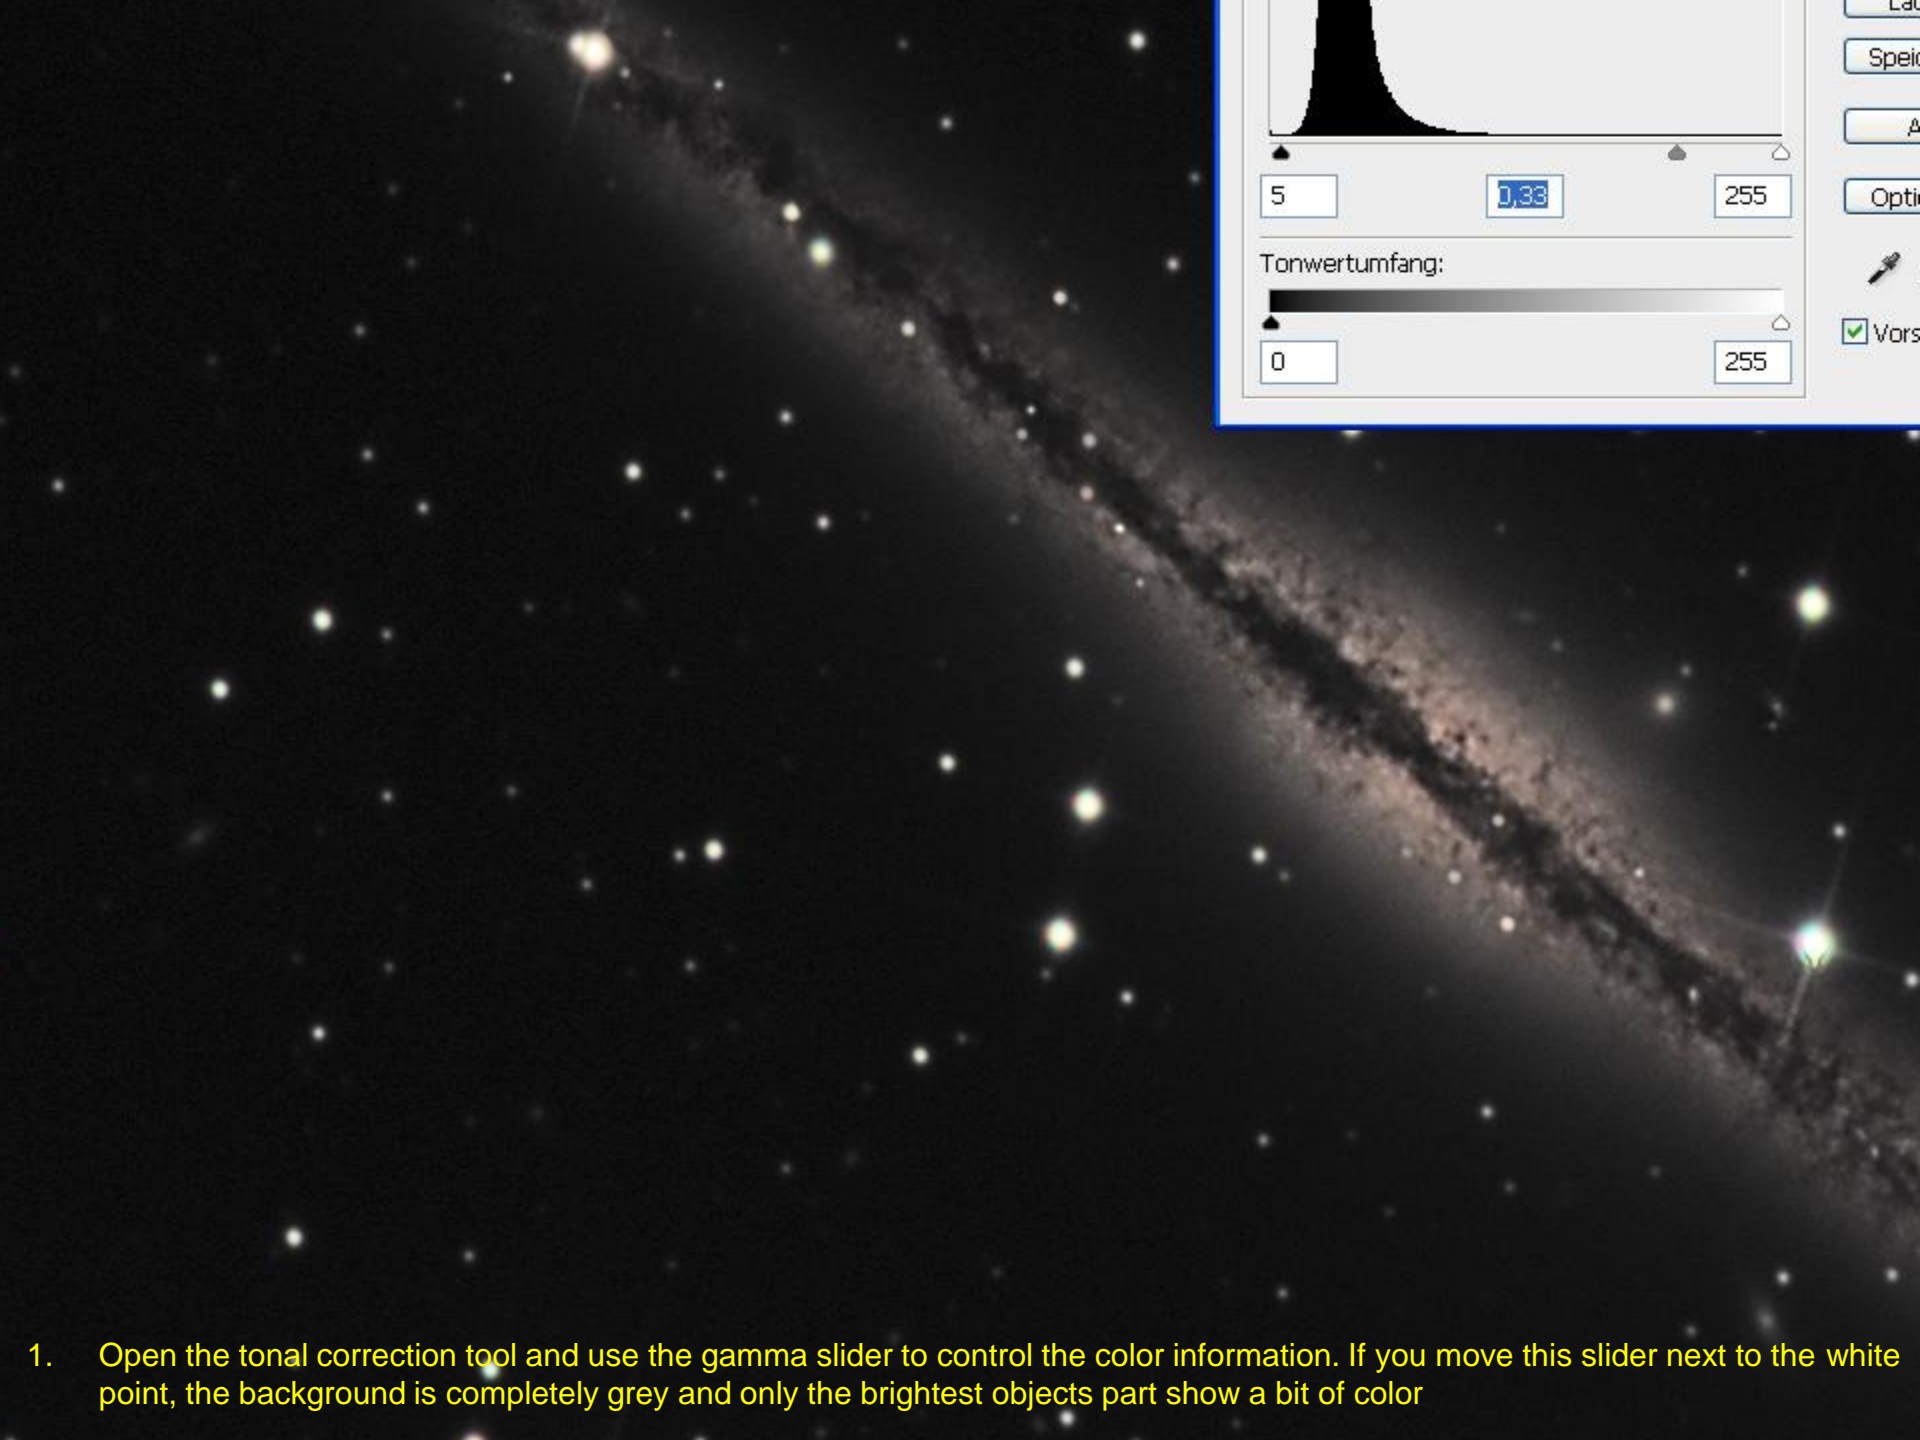

A small thumbnail on the left side of the dialog shows the selected area with the noise reduction settings applied. The background of the dialog is a larger view of the same area. A blue arrow points to the 'JPEG-Artefakt entfernen' checkbox.

Select the weak SN areas with much noise and reduce the (color) noise by using Photoshops „Reduce-noise“ filter. You don't need to pronounce details

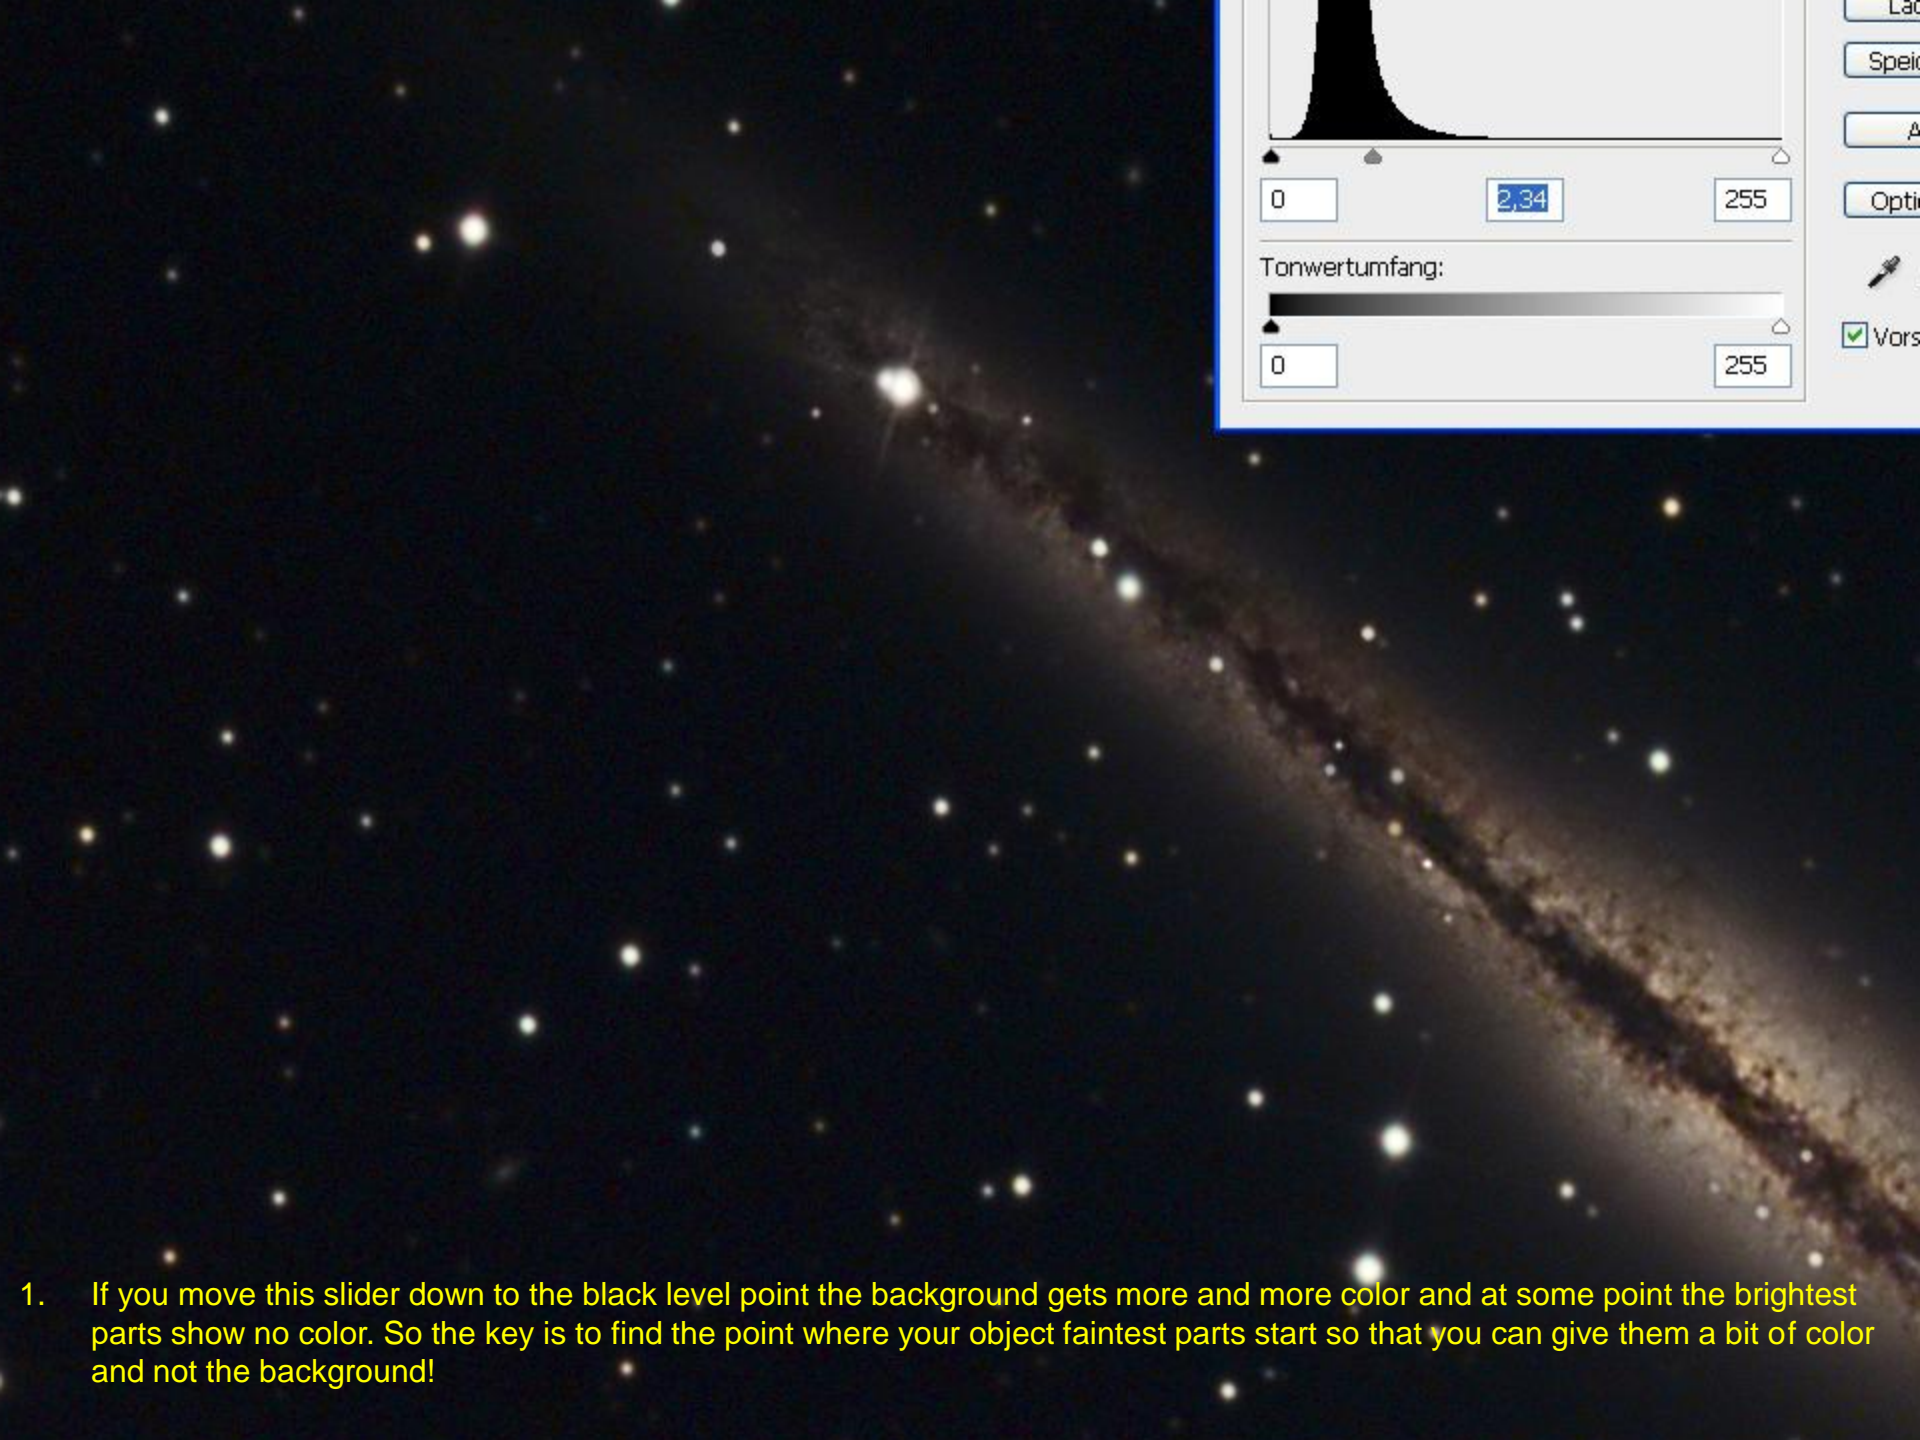

1. The image still shows some color background noise but you are able to control at which low level point color information begins which will shown now!

1. Open the tonal correction tool and use the gamma slider to control the color information. If you move this slider next to the white point, the background is completely grey and only the brightest objects part show a bit of color

0 2,34 255

Tonwertumfang:

0 255

Lad...  
Speic...  
A...  
Opti...  
Vors...

1. If you move this slider down to the black level point the background gets more and more color and at some point the brightest parts show no color. So the key is to find the point where your object faintest parts start so that you can give them a bit of color and not the background!

1. If you are not sure move the gamma slider, click ok and raise the contrast to an extreme point so that you can easily check out if your background got color. If that's the case go back in your protocol and move the gamma slider more to the white point.

# Color contrast boost (1)

# Color contrast boost (2)

The screenshot displays the Adobe Photoshop CS3 Extended interface. The main window shows a starry image of a galaxy. The 'Gradationskurven' (Curves) panel is open, showing the RGB channel. The curve is being adjusted to boost contrast. The panel includes the following options:

- Vorgabe: Benutzerdefiniert
- Kanal: RGB
- Buttons: OK, Abbrechen, Glätten, Auto, Optionen...
- Checkbox:  Vorschau
- Labels: Ausgabe, Eingabe
- Buttons:  Beschneidung anzeigen
- Section: Kurven-Anzeigeoptionen
- Radio buttons: Betrag anzeigen für:  Licht (0-255),  Pigment/Druckfarbe %
- Checkboxes: Einblenden:  Kanalüberlagerungen,  Grundlinie,  Histogramm,  Schnittlinie

The Windows taskbar at the bottom shows the Start button, taskbar icons for Photoshop, Samba, Mozilla Firefox, Microsoft PowerPoint, and Posteingang - Thund..., and the system tray with the date and time (23:45).

If needed, raise again the color contrast of your object in an LRGB and lower the contrast of faint or background inform. to avoid noise

**conclusion: the weaker the signal, the longer the image processing takes!**

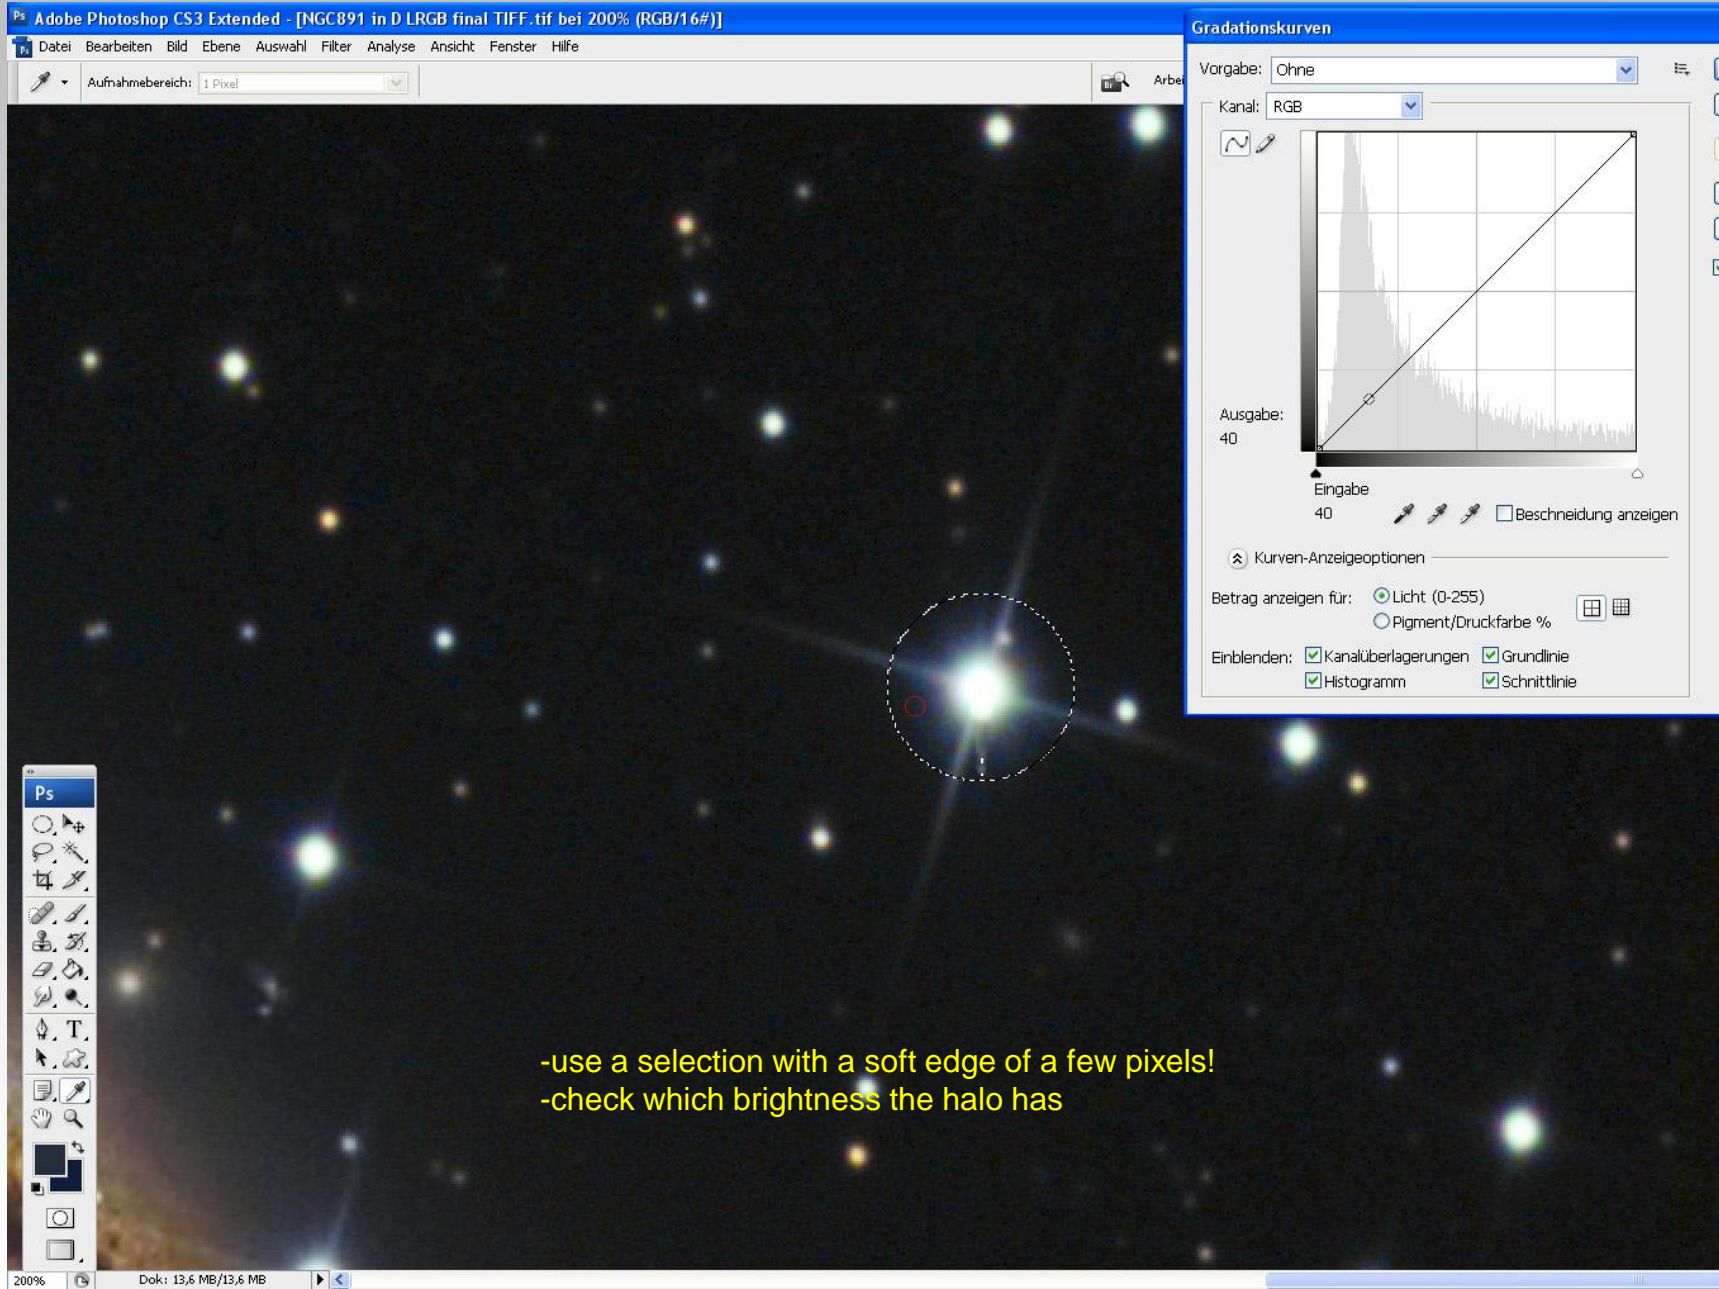

(my workflow is nearly the same for all images, but getting good contrast, especially for color, is much easier with high SN=dark skies)

Comparison 15inch 1,9" backyard to 24inch 1,3" Crete  
(15" image upsized to 24" focal length)

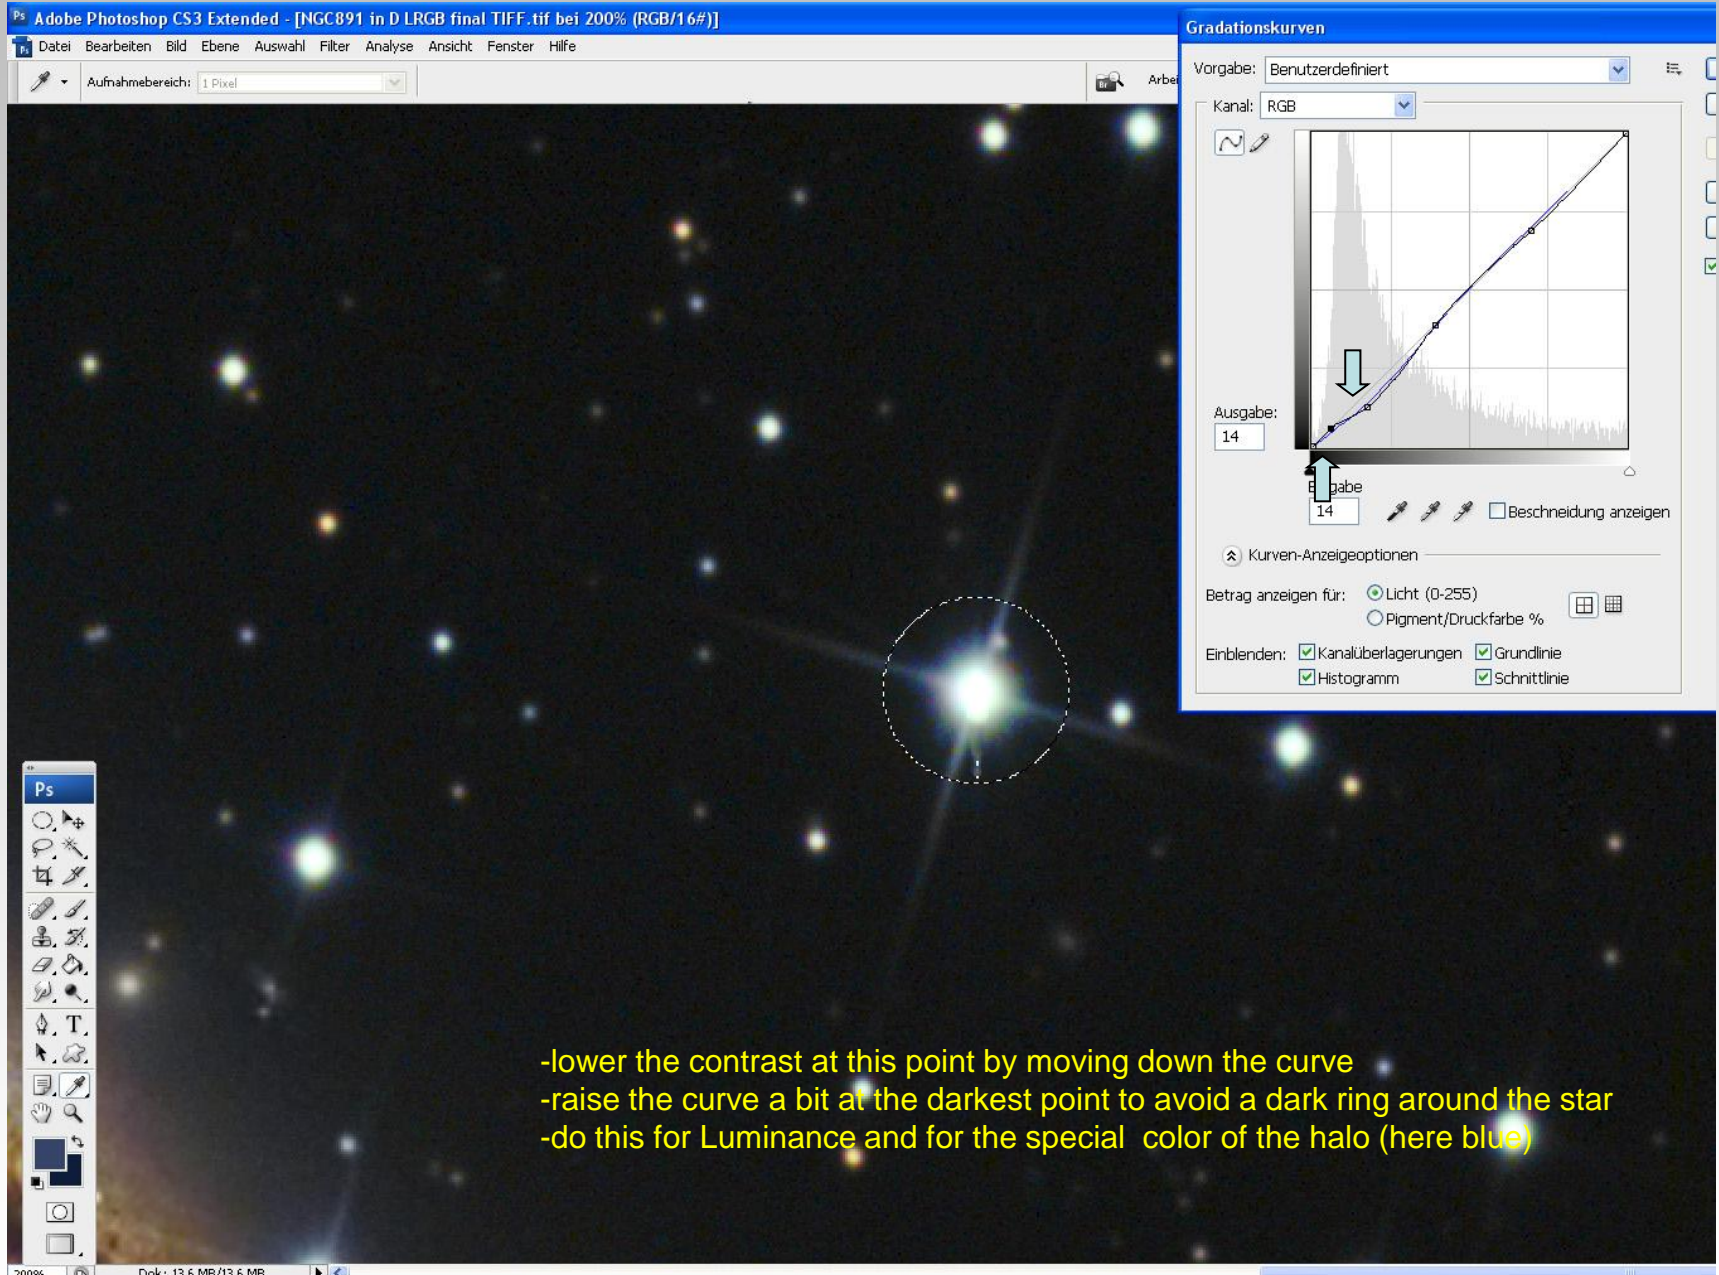

# Reduce star halos 1:

-use a selection with a soft edge of a few pixels!  
-check which brightness the halo has

# Reduce star halos 2:

- lower the contrast at this point by moving down the curve
- raise the curve a bit at the darkest point to avoid a dark ring around the star
- do this for Luminance and for the special color of the halo (here blue)

## Reduce star halos 3:

- reduce the unnatural colors by lowering the saturation of these colors (here cyan and green)
- if needed use the Curves again using a smaller selection around the star
- if needed use the radial Gauss filter
- add some noise back so that the star noise fits to the background noise
- use the minimum filter as a personal taste for a star size reduction

# NGC6946, backyard image, 2,1" (how to get contrast and detail):

1. Stretched raw data
2. Deconvolution using PixInsight
3. High Pass filtering in Photoshop
4. Unsharp masking with small amount and a large radius
5. Kodak GEM for noise reduction

# The center of M51 (how to get contrast and detail):

(the data of this image was aquired by the Capella observatory team [www.capella-observatory.com](http://www.capella-observatory.com))

M51 DDP stretch in CCDStack

# Synthetic flats using PixInsight (1) ([www.plejades-astrophoto.com](http://www.plejades-astrophoto.com))

M51 with obviously visible vignetting:

# Synthetic flats using PixInsight (2)

Open image in freeware PixInsight LE, use the Dynamic Background Extractor (DBE):

# Synthetic flats using PixInsight (3)

Create the mask:

# Synthetic flats using PixInsight (4)

Use Pixel Math and subtract the mask from the Original:

What's possible compared with the Hubble telescope?

(NGC 604 image with about 1,1" made with 24" Ganymed)

What's possible compared with Hubble telescopes?

# IC 4593 in Hercules (diameter 17")

(best seeing so far in Crete – about 0,8" FWHM)

# IC 4593 upscaled to the Hubble image

What's the future for amateur astrophotographers? Active optics???

Thanks for your attention!
